Problem

Time series classification originated from the K dynamical systems of the form

$$\begin{cases} \frac{d}{dt} \bar{\mathbf{x}}(t) = f(\bar{\mathbf{x}}), \\ \bar{\mathbf{x}}(0) = \bar{\mathbf{x}}_0, \end{cases} \quad (1)$$

assuming we have labeled sample series

$\mathcal{D} = \{(\mathbf{x}_1(t_i), y_1), \dots, (\mathbf{x}_N(t_i), y_N)\}$ where $\mathbf{x}(t_i) = \bar{\mathbf{x}}(t_i) + \epsilon(t_i)$.

Time series from different systems

Classification overview

- 1 Reconstruct (if needed) diffeomorphic phase trajectories from the observed time series: Whitney or Takens embedding theorem.

$$\{\tilde{\mathbf{x}}(t_i)\} \rightarrow \{\bar{\mathbf{x}}(t_i)\}$$

- 2 Learn (if not provided) vector fields of the systems $f_i(\mathbf{z})$ from the trajectories (NODE).

$$\hat{f} = \arg \min_{f \in \mathcal{F}} \mathcal{L}(\{\mathbf{x}(t_i)\}, f)$$

Choose $\mathcal{L}, \mathcal{F}$ according to the prior knowledge of the system.

- 3 Associate a test trajectory with the system that gives least deviation from the *initial value problem* (IVP) (1).

$$k = \arg \min_{k \in 1 \dots K} \rho(\{\mathbf{x}(t_i)\}, \text{IVP}(t_i, f_k, \bar{\mathbf{x}}_0))$$

Approach limitations

In steps 2-3 we need to compute precise IVP trajectories and know exact $\bar{\mathbf{x}}_0$. On practice, it is not possible for several reasons

- 1 In many cases IVP has no analytic solution and *numerical solvers* are used. They induce numerical error and may have stability issues.
- 2 Learned field $\hat{f}$ from step 2 is an approximation of the real f . It contributes to the IVP error.
- 3 Observed series $\mathbf{x}_{t_i}$ are noisy including starting point $\bar{\mathbf{x}}_0$.
- 4 The dynamical system (1) may not be an adequate time series model globally. For example, the SDE model may be more appropriate

$$\begin{cases} d\bar{\mathbf{x}}(t) = f(\bar{\mathbf{x}})dt + GdW(t), \\ \bar{\mathbf{x}}(0) = \bar{\mathbf{x}}_0, \end{cases} \quad (2)$$

Classification as the filtering problem

We use ODE solvers to approximate dynamics (1) and obtain the following state space model

$$\begin{aligned}\bar{\mathbf{x}}_{t_{i+1}} &= \text{ODESolve}(\bar{\mathbf{x}}_{t_i}) \\ \mathbf{x}_{t_i} &= \bar{\mathbf{x}}_{t_i} + \epsilon_{t_i} \\ \bar{\mathbf{x}}_0 &\sim F(\mathbf{x})\end{aligned}$$

In this formulation we change $\text{IVP}(t_i, f_k, \bar{\mathbf{x}}_0)$ for $\mathbb{E}[\{\bar{\mathbf{x}}_{t_i}\}|\{\mathbf{x}_{t_i}, \bar{\mathbf{x}}_0\}]$ — the filtering problem. The classifier is now

$$k = \arg \min_{k \in 1 \dots K} \rho(\{\mathbf{x}(t_i)\}, \mathbb{E}[\{\bar{\mathbf{x}}_{t_i}\}|\{\mathbf{x}_{t_i}, \bar{\mathbf{x}}_0\}]).$$

For the SDE dynamics we just obtain more general filtering problem

$$\begin{aligned}\bar{\mathbf{x}}_{t_{i+1}} &= \text{ODESolve}(\bar{\mathbf{x}}_{t_i}) + \xi_{t_{i+1}} \\ \mathbf{x}_{t_i} &= \bar{\mathbf{x}}_{t_i} + \epsilon_{t_i} \\ \bar{\mathbf{x}}_0 &\sim F(\mathbf{x})\end{aligned}$$

Experiments to justify filtering

Compare direct ODE solvers and filtering for the noisy trajectory of the ODE system $\dot{x} = x$

Compare direct ODE solvers and filtering for the noisy trajectory of the SDE system $dx_t = x_t(1 + dW_t)$

Выносятся на защиту

- 1 Предложен метод классификации временных рядов в модели ODE/SDE с учётом случайного шума.
- 2 Получены теоретические результаты асимптотической оптимальности классификатора при достаточной информации о дин.системах и начальной точки. Обоснован подход с фильтрацией при отсутствии данных условий.
- 3 Подход эмпирически валидирован на синтетических и реальных данных.
